## Lecture 21

# Overview

---

A common application of graph criteria is to **program source**

**Graph** : Usually the control flow graph (CFG)

**Node coverage** : Execute every statement

**Edge coverage** : Execute every branch

**Loops** : Looping structures such as for loops, while loops, etc.

**Data flow coverage** : Augment the CFG

- **defs** are statements that assign values to variables
- **uses** are statements that use variables

# Control Flow Graphs

---

A CFG **models** all executions of a method by describing control structures

**Nodes** : Statements or sequences of statements  
(basic blocks)

**Edges** : Transfers of control

**Basic Block** : A sequence of statements such that if the first statement is executed, all statements will be (no branches)

CFGs are sometimes annotated with extra information  
branch predicates

- **defs**
- **uses**

Rules for translating statements into graphs ...

# CFG : The if Statement

```
if (x < y)
{
  y = 0;
  x = x + 1;
}
else
{
  x = y;
}
```

```
if (x < y)
{
  y = 0;
  x = x + 1;
}
```

# CFG : The if-Return Statement

```
if (x < y)
{
    return;
}
print (x);
return;
```

No edge from node 2 to 3.  
The return nodes must be distinct.

# Loops

---

Loops require “*extra*” nodes to be added

Nodes that do not represent statements or basic blocks

# CFG : while and for Loops

```
x = 0;  
while (x < y)  
{  
    y = f (x, y);  
    x = x + 1;  
}  
return (x);
```

# CFG : while and for Loops

```
for (x = 0; x < y; x++)  
{  
    y = f (x, y);  
}  
return (x);
```

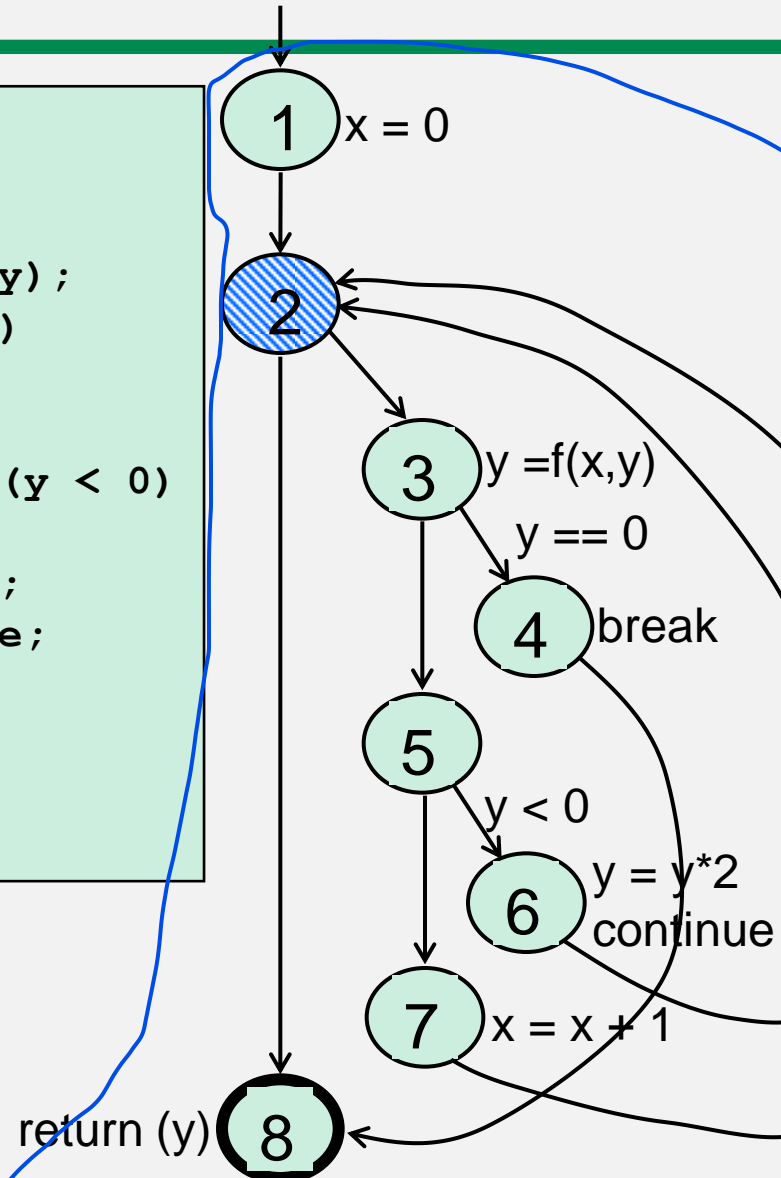

# CFG : do Loop, break and continue

```
x = 0;  
do  
{  
    y = f (x, y);  
    x = x + 1;  
} while (x < y);  
return (y);
```

```
x = 0;  
while (x < y)  
{  
    y = f (x, y);  
    if (y == 0)  
    {  
        break;  
    } else if (y < 0)  
    {  
        y = y*2;  
        continue;  
    }  
    x = x + 1;  
}  
return (y);
```

# CFG : The case (switch) Structure

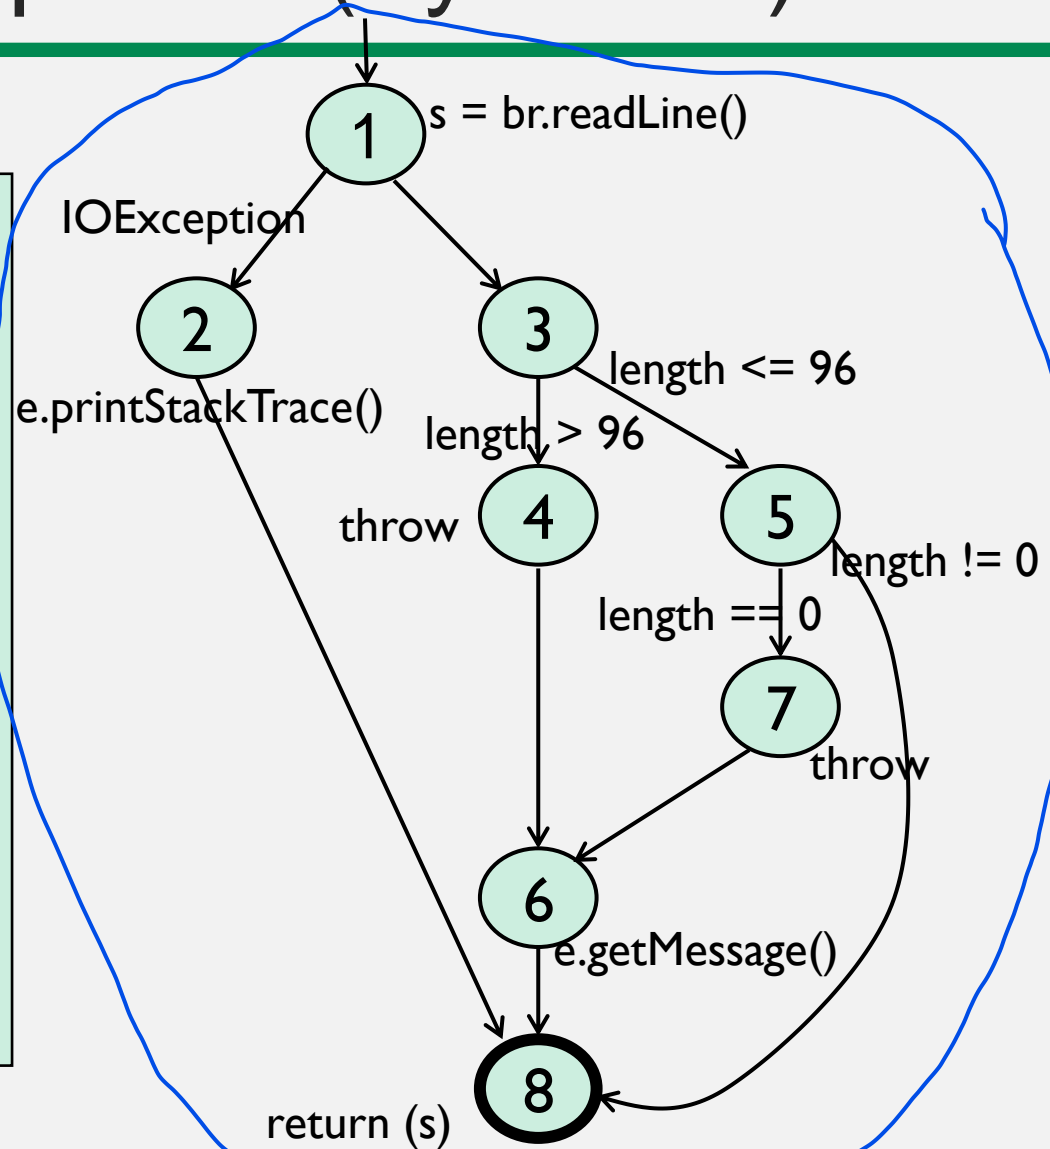

```
read ( c ) ;  
switch ( c )  
{  
    case 'N' :  
        z = 25;  
    case 'Y' :  
        x = 50;  
        break;  
    default:  
        x = 0;  
        break;  
}  
print (x) ;
```

Cases without breaks fall through to the next case

# CFG : Exceptions (try-catch)

```
try
{
    s = br.readLine();
    if (s.length() > 96)
        throw new Exception
            ("too long");
    if (s.length() == 0)
        throw new Exception
            ("too short");
} (catch IOException e) {
    e.printStackTrace();
} (catch Exception e) {
    e.getMessage();
}
return (s);
```

# Example Control Flow – Stats

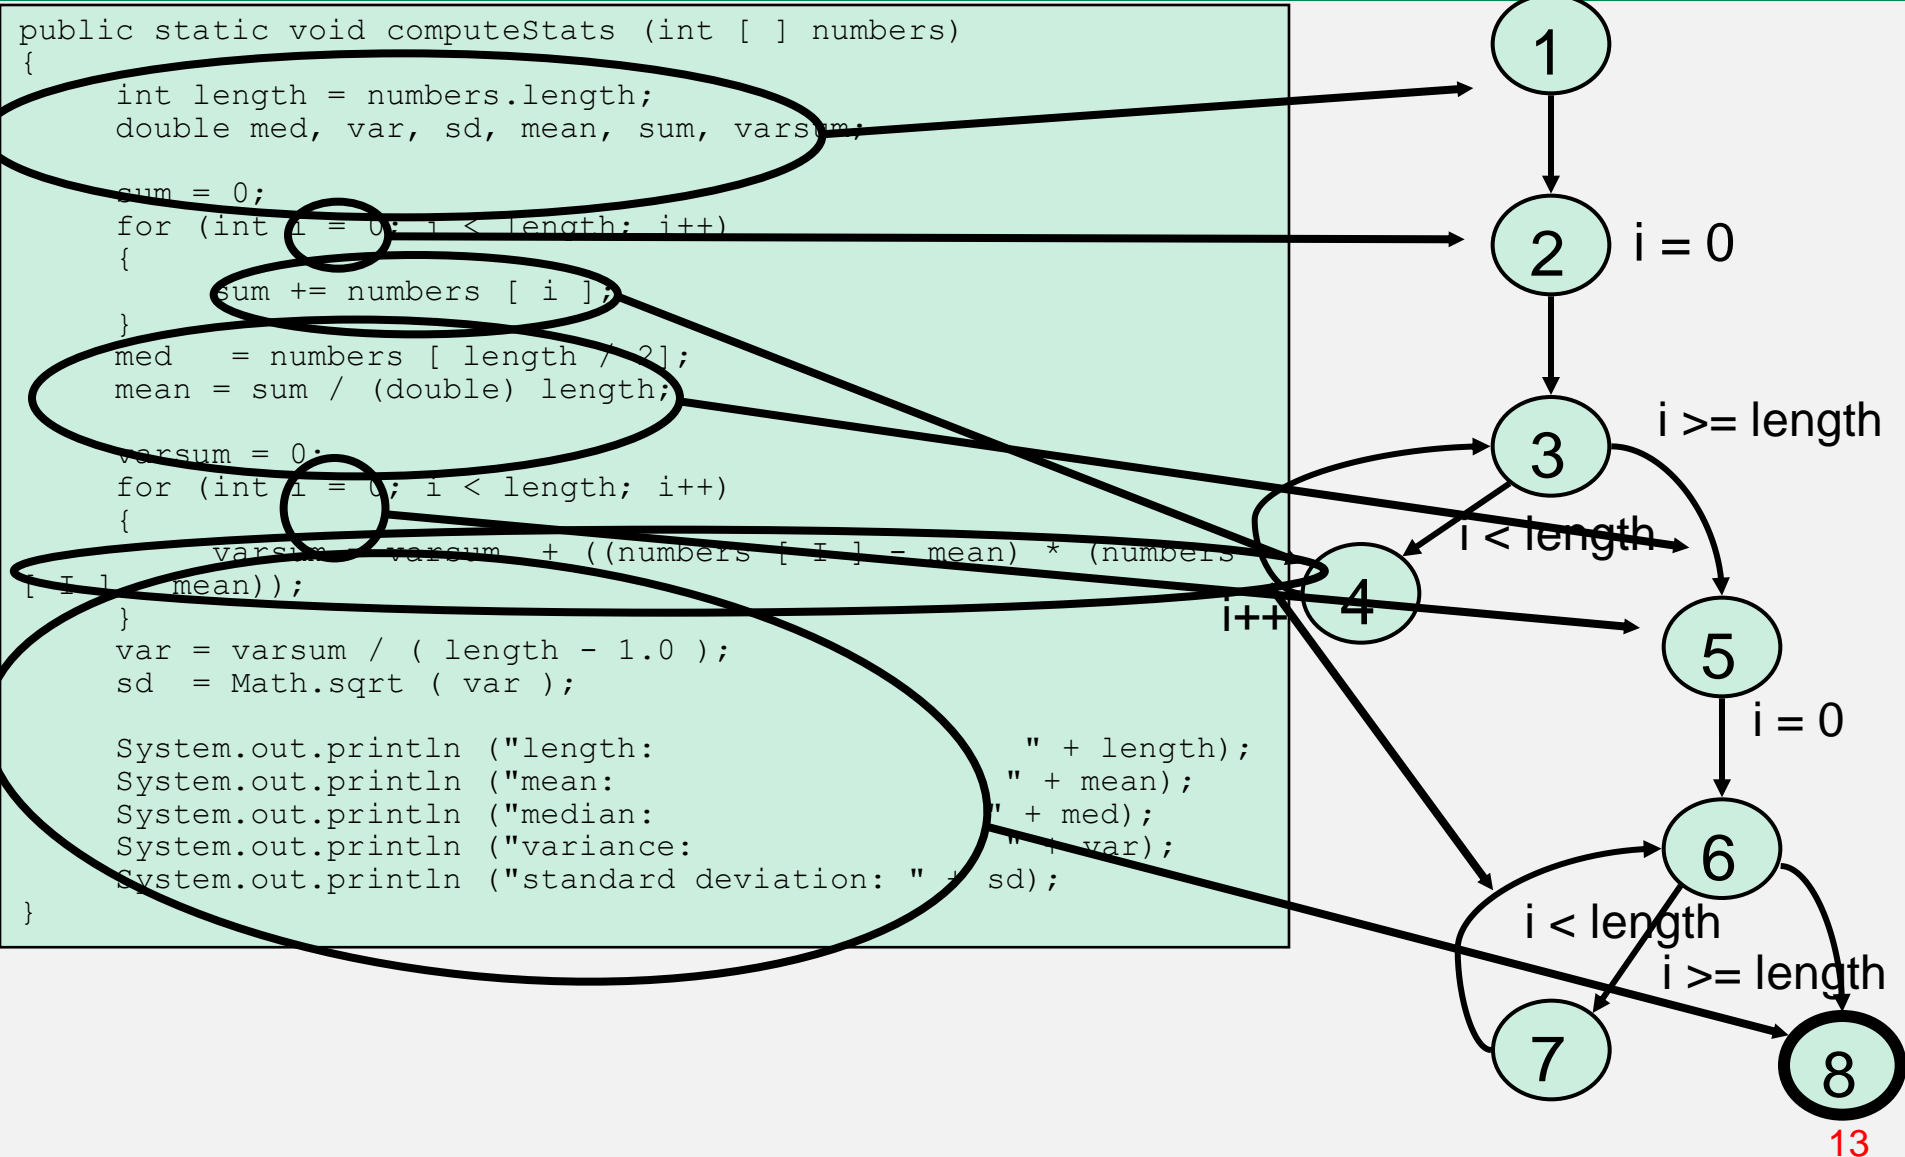

```
public static void computeStats (int [ ] numbers)
{
    int length = numbers.length;
    double med, var, sd, mean, sum, varsum;

    sum = 0;
    for (int i = 0; i < length; i++)
    {
        sum += numbers [ i ];
    }
    med    = numbers [ length / 2];
    mean = sum / (double) length;

    varsum = 0;
    for (int i = 0; i < length; i++)
    {
        varsum = varsum + ((numbers [ i ] - mean) * (numbers [ i ] - mean));
    }
    var = varsum / ( length - 1.0 );
    sd  = Math.sqrt ( var );

    System.out.println ("length:           " + length);
    System.out.println ("mean:           " + mean);
    System.out.println ("median:         " + med);
    System.out.println ("variance:       " + var);
    System.out.println ("standard deviation: " + sd);
}

# Data Flow Coverage for Source

**def** : a location where a value is stored into memory

- x appears on the left side of an assignment (`x = 44;`)

- x is an actual parameter in a call and the method changes its value

- x is a formal parameter of a method (implicit def when method starts)

- x is an input to a program

**use** : a location where variable's value is accessed

- x appears on the right side of an assignment

- x appears in a conditional test

- x is an actual parameter to a method

- x is an output of the program

- x is an output of a method in a return statement

If a def and a use appear on the same node, then it is only a DU-pair if the def occurs after the use and the node is in a loop

# Example Data Flow – Stats

```
public static void computeStats (int [ ] numbers)
{
    int length = numbers.length;

    sum = 0.0;
    for (int i = 0; i < length; i++)
    {
        sum += numbers [ i ];
    }
    med    = numbers [ length / 2 ];
    mean = sum / (double) length;

    varsum = 0.0;
    for (int i = 0; i < length; i++)
    {
        varsum = varsum + ((numbers [ i ] - mean) * (numbers [ i ] - mean));
    }
    var = varsum / ( length - 1 );

# Summary

---

- Applying the graph test criteria to control flow graphs is relatively straightforward
  - Most of the developmental research work was done with CFGs
- A few subtle decisions must be made to translate control structures into the graph
- Some tools will assign each statement to a unique node
  - These slides and the book uses basic blocks
  - Coverage is the same, although the bookkeeping will differ
